## $\Delta$ -based coloring

- ▶ Graph  $G = (V, E)$  with  $n$  vertices and max degree  $\Delta$
- ▶ **Vertex coloring**: assign a color to each vertex  $G$  so that no edge connects two vertices of the same color

- ▶ Finding vertex colorings with a *minimum* number of colors is NP-hard
- ▶  $\Delta$ -based colorings use number of colors depending on  $\Delta$ .
  - ▶ Greedy algorithm:  $\Delta + 1$  colors
  - ▶ Linial's algorithm[Linial92]:  $O(\Delta^2)$  colors
  - ▶ Brook's theorem:  $\Delta$  colors (if possible)

*To what extent is randomization necessary for streaming algorithms that compute a  $\Delta$ -based coloring?*

# Outline

Deterministic multi-pass  $(\Delta + 1)$  coloring

Adversarially robust coloring with  $O(\Delta^{2.5})$  colors

# Deterministic multi-pass $(\Delta + 1)$ -coloring on a graph stream

## Input:

- ▶ A graph  $G = (V, E)$  on  $n$  vertices with maximum degree  $\Delta$ , provided as a sequence of edges

## Processing:

- ▶ Limited working space: only “*semi-streaming*” ( $\tilde{O}(n)$ , where  $\tilde{O}(\cdot)$  hides polylog factors in  $n$  and  $\Delta$ .)<sup>†</sup>
- ▶ For each pass, algorithm reads the input edge sequence in order

## Output:

- ▶ A coloring  $\chi : V \rightarrow [\Delta + 1]$ , so that if  $\{u, v\} \in E$ , then  $\chi(u) \neq \chi(v)$

---

<sup>†</sup>Storing  $G$  takes  $\tilde{O}(n\Delta)$  space.

# Deterministic multi-pass $(\Delta + 1)$ -coloring on a graph stream

## Input:

- ▶ A graph  $G = (V, E)$  on  $n$  vertices with maximum degree  $\Delta$ , provided as a sequence of edges

## Processing:

<sup>†</sup>Storing  $G$  takes  $\tilde{O}(n\Delta)$  space.

## Selected prior work

- ▶ The standard greedy algorithm can  $(\Delta + 1)$ -color a graph of max degree  $\Delta$ , but has no semi-streaming implementation
- ▶ [AssadiChenKhanna19] Single-pass randomized streaming algorithm for  $(\Delta + 1)$  coloring, using semi-streaming space
- ▶ [AssadiChenSun22] No 1-pass deterministic semi-streaming algorithms for even coloring a graph with  $\text{poly}(\Delta)$  colors
- ▶ [AssadiChenSun22] But with  $O(\log \Delta)$  passes, can obtain an  $O(\Delta)$  coloring

### Question

Is there a multi-pass deterministic semi-streaming space algorithm for  $\Delta + 1$  coloring?

- ▶ [GhaffariKuhn21] Deterministic  $(\Delta + 1)$  coloring algorithm in the “LOCAL” and “CONGEST” models of distributed algorithms. [HalldórssonNolinKuhnTonoyan22] “degree + 1” coloring

## Selected prior work

## Our results

### Theorem

*There is a deterministic streaming algorithm for  $(\Delta + 1)$ -coloring which uses  $O(\log \Delta \log \log \Delta)$  passes and  $O(n(\log n)^2)$  space*

### Theorem

*Same bounds hold for (degree+1) list coloring (D1LC), where each vertex  $x \in V$  has associated list  $L_x$  of permitted colors, where  $|L_x| \geq \deg x + 1$ .*

- ▶ Issue: storing color lists would take up to  $\tilde{O}(n\Delta)$  space. See paper.

## High level description for deterministic $\Delta + 1$ coloring

- ▶ Will repeatedly fix colors for more vertices
- ▶ Propose colors for all unfixed vertices, with few monochromatic edges  $\implies$  can fix a constant fraction of proposed colors
- ▶ Example:

- ▶ Example:

# Deterministic color proposal

Progressively restrict which colors each vertex may have.

- ▶ Assign each uncolored vertex set  $[\Delta + 1]$  of all colors
- ▶ Repeatedly choose a subset of the current color set for each vertex
  - ▶ Have a cost function<sup>‡</sup> bounding the final number of monochromatic edges
  - ▶ Pass 1: Compute “slack” values<sup>§</sup>, where if  $x$  has color set  $S$ , then

$$\text{slack}(x, S) = |S| - |\{\{y, x\} \in E : y\text{'s color fixed and in } S\}|$$

- ▶ Pass 2-3: Use hash family to search for good color subset assignment
- ▶ After  $O(\log \Delta)$  refinements, have a single proposed color for every vertex.

---

<sup>‡</sup>Similar: [Kuhn20] and [GhaffariKuhn21]

# Adversarially robust<sup>¶</sup> streaming algorithms

- ▶ Two player game between Algorithm and Adversary
- ▶ Adversary constructs series of inputs  $e_1, e_2, \dots, e_i$ , and Algorithm produces outputs  $\chi_1, \dots, \chi_i$  solving task for stream up to this point.
- ▶ Adversary's chosen inputs may depend on prior outputs of the Algorithm.
- ▶ Algorithm is “adversarially robust” if it has low error rate against *any* Adversary strategy
  - ▶ Example: Input generated in real time – outputs may influence future inputs
  - ▶ Sub-component of larger algorithm

<sup>¶</sup>See [Ben-EliezerJayaramWoodruffYogev20] for more explanation

# High level description of $O(\Delta^{2.5})$ -coloring algorithm

Different forms of product coloring algorithm are efficient for different edge insertion patterns.

“Slow” vertices

- ▶  $\leq \sqrt{\Delta}$  incident edges in a batch of  $n$
- ▶ Time-linked product coloring instances

“Fast” vertices

- ▶  $> \sqrt{\Delta}$  incident edges in a batch of  $n$
- ▶ Degree-linked product coloring instances

# High level description of $O(\Delta^{2.5})$ -coloring algorithm

Different forms of product coloring algorithm are efficient for different edge insertion patterns.

## Summary

- ▶ A *multi-pass deterministic* streaming algorithm which outputs a  $(\Delta + 1)$ -vertex-coloring of an input graph of max degree  $\leq \Delta$ , using semi-streaming space.
- ▶ A single-pass *adversarially robust* streaming algorithm which outputs an  $O(\Delta^{2.5})$ -vertex-coloring of an input graph of max degree  $\leq \Delta$ , using semi-streaming space (& long random string).
- ▶ **Open problems:**
  - ▶ Is there a 2-pass deterministic streaming algorithm in semi-streaming space using  $O(\Delta)$  colors?
  - ▶ Is there an adversarially robust streaming algorithm in semi-streaming space using  $O(\Delta^2)$  colors, and  $\tilde{O}(n)$  bits of randomness?
